The stress-strain curve has a positive slope beyond the elastic limit, i.e., in the plastic range the stress required to cause further deformation increases with increasing strain, a phenomenon called work-hardening or strain-hardening occurs.

Plasticity in metals is usually a consequence of dislocations.

Plasticity (physics) - Wikipedia

Strain is a measure of deformation representing the displacement between particles in the body relative to a reference length. A general

deformation of a body can be expressed in the form $x = F(X)$ where X is the reference position of material points in the body. Such a measure does not distinguish between rigid body motions (translations and rotations) and changes in shape (and size) of the body.
